

A frozen late-layer SAE panel shows replicated carry-selective logit control

The Top-10 primary was null; the exploratory Top-20 panel was frozen and tested once on intervention-untouched cases

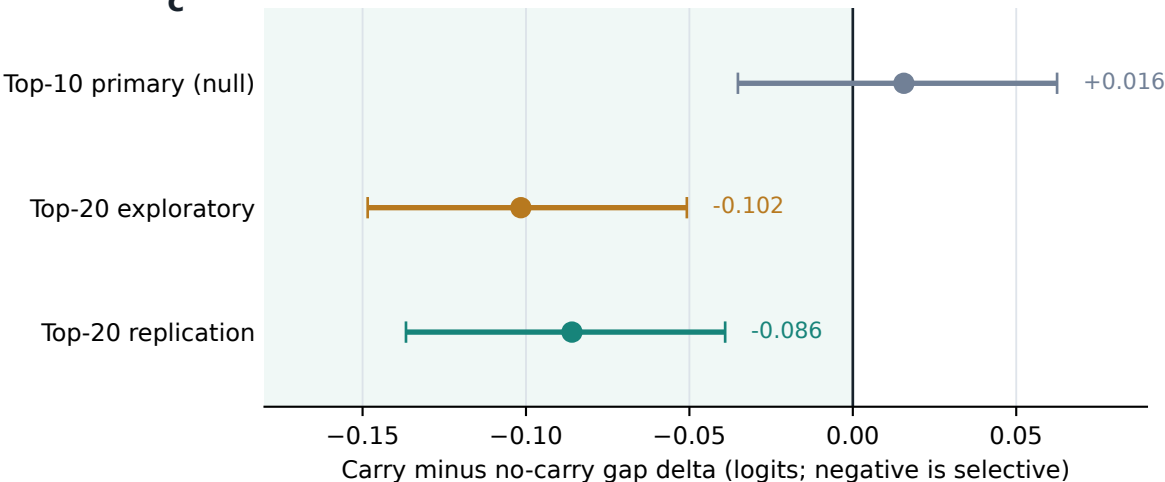

a Raw MLP carry decodability

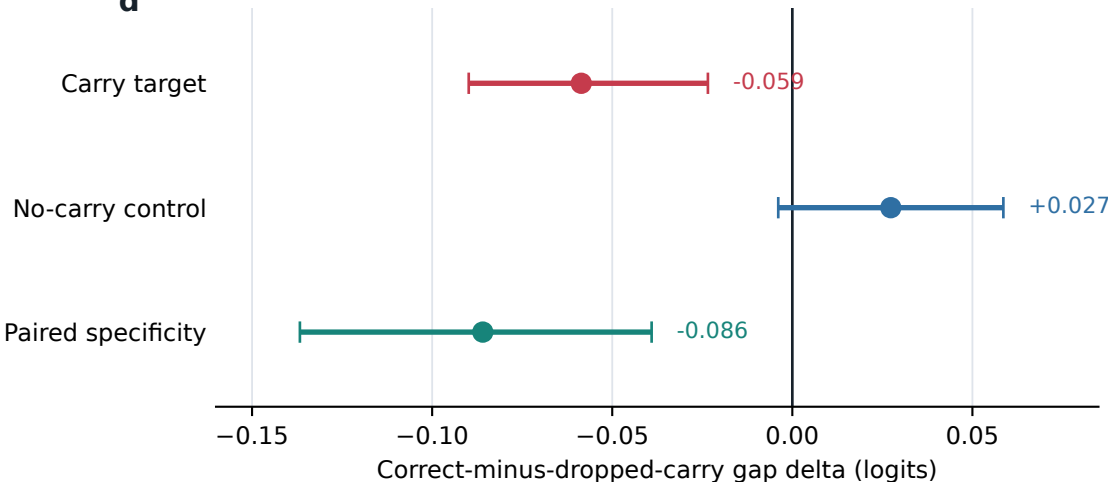

b Frozen carry-associated panel (20 latents)

c From null primary to frozen replication

d Independent untouched-case test ($n = 32$)

Replication criterion passed: 62.5% of pairs had a more negative carry effect; top-token transfer fraction = 0.0.

Interpretation: a distributed carry-associated causal panel at the tested MLP sites, not a monosemantic carry bit, answer flip, or complete addition circuit.
