

# A frozen late-layer SAE panel shows replicated carry-selective logit control

The Top-10 primary failed; the exploratory Top-20 panel was frozen and tested once on intervention-untouched cases

**Replication criterion passed: 62.5% of pairs had a more negative carry effect; top-token transfer fraction = 0.0.**

Interpretation: a distributed carry-associated causal panel at the tested MLP sites, not a monosemantic carry bit, answer flip, or complete addition circuit.
